

# Package: rlecuyer (via r-universe)

September 10, 2024

**Version** 0.3-7

**Date** 2023-03-23

**Title** R Interface to RNG with Multiple Streams

**Description** Provides an interface to the C implementation of the random number generator with multiple independent streams developed by L'Ecuyer et al (2002). The main purpose of this package is to enable the use of this random number generator in parallel R applications.

**License** GPL (>= 2)

**URL** <http://www.iro.umontreal.ca/~lecuyer/myftp/papers/streams00.pdf>

**NeedsCompilation** yes

**Repository** <https://hanase.r-universe.dev>

**RemoteUrl** <https://github.com/hanase/rlecuyer>

**RemoteRef** HEAD

**RemoteSha** c4fb7af7ae4bbe8e085daf4a3c4fae1d63cffce1

## Description

Provides an interface to the C implementation of the random number generator (RNG) with multiple independent streams developed by L'Ecuyer et al (2002). The package enables to use this random number generator in parallel R applications.

## Details

When the **rlecuyer** package is loaded, the L'Ecuyer RNG is initialized by creating a global table object (`.lec.Random.seed.table`) which allows to keep information and account for multiple random number streams that the user can create. The individual streams are identified by names which must be unique. The workflow starts with initializing the RNG with a seed via `.lec.SetPackageSeed` and creating one or more streams via `.lec.CreateStream`.

When the RNG is deployed in a parallel application, one stream can be used for generating all random numbers (RNs) on one node, or all RNs generated within one task. The master node would hold the global table object, initialize it with a package seed (via `.lec.SetPackageSeed`), create the amount of streams that are needed for the application (via `.lec.CreateStream`) and send each worker information about the stream assigned to it. Alternatively, all workers could be initialized with an identical global table and identical streams, and the master node could be only sending the identifiers of the streams on which each worker should operate. If streams are assigned to tasks instead of nodes, one can assure reproducibility regardless of the number of nodes the application is running on, or regardless if it is run sequentially or in parallel.

To generate RNs from a particular stream, start with the function `.lec.CurrentStream`. This will assure that any subsequent call to standard R functions that use RNs (e.g. `runif` or `rnorm`) will draw from the current stream. `.lec.CurrentStreamEnd` unsets the stream. Thus, by using these two functions in pair, one can switch between different streams. Alternatively, if drawing from a uniform distribution is sufficient, by using the function `.lec.uniform` one can omit the `CurrentStream` and `CurrentStreamEnd` pair, as the `.lec.uniform` function includes the name of the stream to draw from.

Each stream is given by its current state (see `SetPackageSeed` for description) that can be viewed by `.lec.WriteStateFull`. To reset a stream to its initial state, use `.lec.ResetStartStream`. To extract the current state of a stream, one can use `.lec.GetState`.

Other useful functions are available. For example, one can advance the state of a stream by given number of steps via the `.lec.AdvanceState` function. Function `.lec.GetStreams` allows to retrieve names of all streams in the global table. To delete a stream from the table, use `.lec.DeleteStream`. If there is a need to delete the whole table of streams and initialize a new one, one can use `.lec.init` and `.lec.exit`.

## References

P. L'Ecuyer, R. Simard, E.J.Chen and W.D.Kelton: An Object-Oriented Random-Number Package With Many Long Streams and Substreams; *Operations Research*, vol. 50, nr. 6, 2002.

**Examples**

```

# Initialize the RNG with package seed
seed <- rep(85424, 6)
.lec.SetPackageSeed(seed)

# Create 5 streams
nstream <- 5
snames <- as.character(1:nstream) # unique stream identifiers
.lec.CreateStream(snames)

# Generate 10 RNs from each of the 5 streams
# (each of the iterations could run on a different node)
rns <- NULL
for (i in 1:nstream) {
  old.kind <- .lec.CurrentStream(snames[i])
  rns <- rbind(rns, runif(10))
  .lec.CurrentStreamEnd(old.kind)
}
rns

# Reproduce results on the second stream
.lec.ResetStartStream("2")
rns2 <- .lec.uniform("2", 10)
all(rns2 == rns[2,])

# Reproduce the last three RNs on stream 5
.lec.ResetStartStream("5")
.lec.AdvanceState("5", 0, 7) # move the state by 7 steps
rns5p <- .lec.uniform("5", 3)
all(rns5p == rns[5, 8:10])

```

---

AdvanceState

*Advance the state of a stream*

---

**Description**

`.lec.AdvanceState` advances the state of a stream by  $n$  steps (see below).

**Usage**

```
.lec.AdvanceState (name, e, c)
```

**Arguments**

name	name of the stream.
e, c	if $e > 0$ then $n = 2^e + c$ ; if $e < 0$ then $n = -2^{-e} + c$ ; if $e = 0$ then $n = c$ .

**Details**

`.lec.AdvanceState` is a wrapper function for the C function `RngStream_AdvanceState` (L'Ecuyer et al, 2002).

**Value**

None.

**References**

P. L'Ecuyer, R. Simard, E.J.Chen and W.D.Kelton: An Object-Oriented Random-Number Package With Many Long Streams and Substreams; Operations Research, vol. 50, nr. 6, 2002.

---

CreateStream	<i>Spawn new streams</i>
--------------	--------------------------

---

**Description**

`.lec.CreateStream` creates new streams of random numbers. `.lec.StreamExists` checks the existence of a stream.

**Usage**

```
.lec.CreateStream (names)
.lec.StreamExists (name)
```

**Arguments**

names	a character string or a vector of character strings naming the streams to be created. The argument must be provided and the names must be unique within the set of existing streams. If for one <code>i</code> a stream of the name <code>names[i]</code> already exists, its state is replaced by the state of the new created stream.
name	name of stream

**Details**

`.lec.CreateStream` is a wrapper function for the C function `RngStream_CreateStream` (L'Ecuyer et al, 2002). The state of the created stream returned by the C function is stored in the global object `.lec.Random.seed.table`.

`.lec.StreamExists` returns TRUE if the stream is found in `.lec.Random.seed.table`, otherwise FALSE.

**Value**

`.lec.StreamExists` returns TRUE or FALSE.

## References

P. L'Ecuyer, R. Simard, E.J.Chen and W.D.Kelton: An Object-Oriented Random-Number Package With Many Long Streams and Substreams; Operations Research, vol. 50, nr. 6, 2002.

## Examples

```
nstreams <- 10          # number of streams
names <- paste("mystream", 1:nstreams, sep="")
.lec.CreateStream(names)
.lec.WriteStateFull(names)
```

---

CurrentStream	<i>Set/unset the current stream</i>
---------------	-------------------------------------

---

## Description

`.lec.CurrentStream` sets the current stream for usage with the standard R functions for generating random numbers such as `runif` or `rnorm`. `.lec.CurrentStreamEnd` unsets it.

## Usage

```
.lec.CurrentStream (name)
.lec.CurrentStreamEnd (kind.old = c("Mersenne-Twister",
                                   "Kinderman-Ramage"))
```

## Arguments

name	a character string giving the name of the stream.
kind.old	a length 2 character vector, the old rng kinds (possibly returned by <code>.lec.CurrentStream</code> ).

## Details

`.lec.CurrentStream` sets the `RNGkind` to user-defined. All succeeding calls of R built-in generators will generate random numbers from the stream name, until `.lec.CurrentStreamEnd` is called. `.lec.CurrentStreamEnd` updates the RNG state of the stream name in the table `.lec.Random.seed.table` and sets the `RNGkind` to `kind.old`. These two functions are meant to be always used as a pair. Thus, one can arbitrarily switch generating between different streams.

## Value

`.lec.CurrentStream` returns a two-element character vector of the RNG and normal kinds in use before the call. `.lec.CurrentStreamEnd` returns a character string giving the name of the unset current stream.

**Examples**

```
nstreams <- 10      # number of streams
names <- paste("mystream", 1:nstreams, sep="")
.lec.CreateStream(names)
for (i in 1:nstreams) { # generate 10 RNs from each stream
  old.kind <- .lec.CurrentStream(names[i])
  print(paste("stream no.", i))
  print(runif(10))
  .lec.CurrentStreamEnd(old.kind)
}
```

---

DeleteStream	<i>Remove streams</i>
--------------	-----------------------

---

**Description**

.lec.DeleteStream removes streams from the global state table.

**Usage**

```
.lec.DeleteStream (names)
```

**Arguments**

names	a character string or a vector of character strings naming the streams to be deleted.
-------	---

**Details**

All streams given in the argument names are removed from the table .lec.Random.seed.table.

**Value**

None.

---

GetState	<i>Return current state of a stream</i>
----------	---

---

**Description**

Returns current state (Cg values) of the stream name.

**Usage**

```
.lec.GetState (name)
```

**Arguments**

name                    a character string giving the name of the stream.

**Value**

a vector of six integer values that identifies the current state of the stream.

**See Also**

[SetPackageSeed](#)

---

GetStreams	<i>Return names of existing streams</i>
------------	---

---

**Description**

Returns names of existing streams stored in `.lec.Random.seed.table`.

**Usage**

```
.lec.GetStreams ()
```

**Value**

a vector of character strings.

---

IncreasedPrecis	<i>Switch between 32 and 53 bits of resolution</i>
-----------------	--

---

**Description**

Switch between 32 and 53 bits of resolution as described in L'Ecuyer et al (2002).

**Usage**

```
.lec.IncreasedPrecis (name, incp=FALSE)
```

**Arguments**

name                    name of the stream.  
incp                    see L'Ecuyer et al (2002).

**Details**

`.lec.IncreasedPrecis` is a wrapper function for the C function `RngStream_IncreasedPrecis`.

**Value**

None.

**References**

P. L'Ecuyer, R. Simard, E.J.Chen and W.D.Kelton: An Object-Oriented Random-Number Package With Many Long Streams and Substreams; Operations Research, vol. 50, nr. 6, 2002.

---

init

*Initialization and Cleaning*

---

**Description**

Initialize and remove the RNG

**Usage**

```
.lec.init()
.lec.exit()
```

**Details**

The package uses a global table object `.lec.Random.seed.table` to keep information about the current state of the streams. Functions `.lec.init` creates this global object and function `.lec.exit` deletes it. However, in most cases these two functions will not be needed, as the table is automatically created when the package is loaded and it is deleted when the package is unloaded. If there is however a need to explicitly delete the table of streams and create a new empty one, these two functions can be used for that purpose.

`.lec.init` initializes the workspace: removes old and creates new global object `.lec.Random.seed.table`. It also allocates memory for the current stream used by [.lec.CurrentStream](#).

`.lec.exit` removes the global object `.lec.Random.seed.table` and frees memory used for the current stream.

---

ResetStream

*Reset the state of a stream*

---

**Description**

Resets the state of a stream to its initial state, beginning of the current substream or beginning of the next substream.

**Usage**

```
.lec.ResetNextSubstream(name)  
.lec.ResetStartStream(name)  
.lec.ResetStartSubstream(name)
```

**Arguments**

name                    a character string giving the name of the stream.

**Details**

```
.lec.ResetNextSubstream reinitializes the stream to the beginning of its next substream.  
.lec.ResetStartStream reinitializes the stream to its initial state.  
.lec.ResetStartSubstream reinitializes the stream to the beginning of its current substream.
```

**Value**

None.

**See Also**

[SetPackageSeed](#)

---

SetAntithetic                    *Switch between U and 1-U variates*

---

**Description**

Switches between  $U$  and  $1 - U$  variates.

**Usage**

```
.lec.SetAntithetic (name, anti=FALSE)
```

**Arguments**

name                    name of the stream.  
anti                    if anti=TRUE then antithetic variates are generated (i.e.  $1 - U$ ), until this function is called again with anti=FALSE.

**Value**

None.

---

SetPackageSeed	<i>Set RNG Seed</i>
----------------	---------------------

---

### Description

Set the initial seed of the package or stream.

### Usage

```
.lec.SetPackageSeed(seed)
.lec.SetSeed (name, seed)
```

### Arguments

name	a character string giving the name of the stream.
seed	a vector of six integers. If it is shorter, the seed is extended to the length of 6 by default values 12345. If it is longer, it is truncated to the length of 6 by eliminating the last elements.

### Details

`.lec.SetPackageSeed` sets the the starting state of the next stream to be created. If there are no streams yet, it is the initial seed of the RNG. `.lec.SetSeed` sets the seed of a specific stream.

A state of each stream is given by three integer vectors of length 6: `Ig` gives the initial state of the stream, `Bg` gives the starting state of the substream that contains the current state, `Cg` gives the current state. Function `.lec.SetPackageSeed` sets `Cg`, `Bg` and `Ig` to the value of seed. Function `.lec.SetSeed` sets `Ig` to seed. L'Ecuyer recommends to use the [ResetStream](#) functions instead of `SetSeed`.

### Value

The (possibly modified) seed that has been used.

### See Also

[ResetNextSubstream](#)

### Examples

```
# Set the seed of the first stream
.lec.SetPackageSeed(1:6)

# Create the first stream and print out its state
.lec.CreateStream("A")
.lec.WriteStateFull("A")

# Create two more streams
.lec.CreateStream(c("B", "C"))
```

```
.lec.WriteStateFull(c("A", "B", "C"))

# Cet the seed of the next stream and create it
.lec.SetPackageSeed(rep(5678, 6))
.lec.CreateStream("D")
.lec.WriteStateFull(c("A", "B", "C", "D"))
```

---

uniform

*Generate random numbers*

---

### Description

`.lec.uniform` generates  $U(0, 1)$  random numbers.  
`.lec.uniform.int` generates random numbers from the discrete uniform distribution over integers.

### Usage

```
.lec.uniform (name, n = 1)

.lec.uniform.int (name, n = 1, a = 0, b = 10)
```

### Arguments

name	name of the stream.
n	number of random numbers to be generated.
a, b	interval from which the integer random numbers should be generated.

### Details

`.lec.uniform` and `.lec.uniform.int`, respectively, are wrapper functions for the C functions `RngStream_RandU01` and `RngStream_RandInt`, respectively (L'Ecuyer et al, 2002).

Note: Since the stream is here identified by name, there is no need for using the [CurrentStream](#) pair.

### Value

A vector of  $n$  random numbers.

### References

**Examples**

```
nstreams <- 10      # number of streams
seed<-rep(1,6)
.lec.SetPackageSeed(seed)
names <- paste("mystream",1:nstreams,sep="")
.lec.CreateStream(names)
for (i in 1:nstreams) # generate 10 RNs from each stream
  print(.lec.uniform(names[i],10))
.lec.DeleteStream(names)
```

---

WriteState

*Output of the current state of streams*

---

**Description**

.lec.WriteState writes the current state of given streams (Cg values).

.lec.WriteStateFull writes the values of all internal state variables of given streams.

**Usage**

```
.lec.WriteState (names)
```

```
.lec.WriteStateFull (names)
```

**Arguments**

names            a character string or a vector of character strings naming the streams.

**Value**

None
